# Using Delphi's Open Tools API

## IN THIS CHAPTER

Have you ever thought to yourself, "Delphi is great, but why doesn't the IDE perform this little task that I'd like it to?" If you have, then have no fear. The Open Tools API is for you. The Delphi Open Tools API provides you with the capability of creating your own tools that work closely with Delphi's IDE. In this chapter, you will learn about the different interfaces that make up the Open Tools API, how to use the interfaces, and also how to leverage your newly found expertise to write a fully featured wizard.

# Open Tools Interfaces

The Open Tools API is composed of eight units, each containing one or more objects that provide interfaces to a variety of facilities in the IDE. Using these interfaces enables you to write your own Delphi wizards, version control managers, and component and property editors. You will also gain a window into Delphi's IDE and editor through any of these add-ons.

With the exception of the interfaces designed for component and property editors, the Open Tools interface objects provide an all-virtual interface to the outside world—meaning that using these interface objects involves working only with the objects' virtual functions. You cannot access the objects' data fields, properties, or static functions. Because of this, the Open Tools interface objects follow the COM standard (see Chapter 23, "COM and ActiveX"). With a little work on your part, these interfaces can be used by any programming language that supports COM. In this chapter, you will work only with Delphi, but you should know that the capacity for using other languages is available (in case you just can't get enough of C++).

> **NOTE**
>
> The complete Open Tools API is available only with the Delphi Professional and Client/Server Suite. Delphi Standard has the capability to use add-ons created with the Open Tools API, but it cannot create add-ons because it contains only the units for creating component and property editors. You can find the source code for the Open Tools interfaces in the `\Delphi 5\Source\ToolsAPI` subdirectory.

Table 26.1 shows the units that make up the Open Tools API and the interfaces they provide. The term *interface* is used loosely here because it does not refer to Delphi's native `interface` types. Because the Open Tools API predates Delphi's native interface support, the Open Tools API uses regular Delphi classes with virtual abstract methods as substitutes for true interfaces. The use of true interfaces has been phased into the Open Tools API over the past few versions of Delphi, and the current incarnation of the Open Tools API is primarily `interface`-based.

**TABLE 26.1**   Units in the Open Tools API

| *Unit Name* | *Purpose* |
| --- | --- |
| ToolsAPI | Contains the latest interface-based Open Tools API elements. The contents of this unit essentially supersede the pre-Delphi 5 Open Tools API units that use abstract classes to manipulate menus, notifications, the file system, the editor, and wizard add-ins. It also contains new interfaces for manipulating the debugger, IDE key mappings, projects, project groups, packages, and the To Do list. |
| VirtIntf* | Defines the base TInterface class from which other interfaces are derived. This unit also defines TIStream class, which is a wrapper around a VCL TStream. |
| IStreams* | Defines TIMemoryStream, TIFileStream, and TIVirtualStream classes, which are descendants of TIStream. These interfaces can be used to hook into the IDE's own streaming mechanism. |
| ToolIntf* | Defines TIMenuItemIntf and TIMainMenuIntf classes, which enable the Open Tools developer to create and modify menus in the Delphi IDE. This unit also defines the TIAddInNotifier class, which allows add-in tools to be notified of certain events within the IDE. Most importantly, this unit defines the TIToolServices class, which provides an interface into various portions of the Delphi IDE (such as the editor, component library, Code Editor, Form Designer, and file system). |
| VCSIntf | Defines the TIVCSClient class, which enables the Delphi IDE to communicate with version-control software. |
| FileIntf* | Defines the TIVirtualFileSystem class, which the Delphi IDE uses for filing. Wizards, version-control managers, and property and component editors can use this interface to hook into Delphi's own file system to perform special file operations. |
| EditIntf* | Defines classes necessary for manipulating the Delphi Code Editor and Form Designer. The TIEditReader class provides read access to an editor buffer. TIEditWriter provides write access to the same. TIEditView is defined as an individual view of an edit buffer. TIEditInterface is the base interface to the editor, which can be used to obtain the previously mentioned editor interfaces. The TIComponentInterface class is an interface to an individual component sitting on a form at design time. TIFormInterface is the base interface to a design-time form or data module. TIResourceEntry is an interface for the raw data in a project's resource (*.res) file. TIResourceFile is a higher-level interface to the project resource file. TIModuleNotifier is a class that provides notifications when various events occur for a particular module. Finally, TIModuleInterface is the interface for any file or module open in the IDE. |

*continues*

**TABLE 26.1** Continued

| Unit Name | Purpose |
|---|---|
| ExptIntf* | Defines the abstract `TIExpert` class from which all experts descend. |
| DsgnIntf | Defines the `IFormDesigner` interface and the `TPropertyEditor` and `TComponentEditor` classes, which are used to create custom property and component editors. |

*\*Functionality replaced by the ToolsAPI unit. Exists only for backward compatibility with versions prior to Delphi 5.*

> **NOTE**
>
> You might wonder where all this wizard stuff is documented in Delphi. We assure you that it is documented, but it isn't easy to find. Each of these units contains complete documentation for the interface, classes, methods, and procedures declared within. We will not regurgitate the same information that these units contain, so we urge you to take a look at the units for complete documentation.

## Using the Open Tools API

Now that you know what's what, it is time to get your hands dirty and look at some actual code. This section focuses primarily on writing wizards by using the Open Tools API. We will not discuss the building of version-control systems because the interest for such a topic is arguably limited. For examples of component and property editors, you should look at Chapter 21, "Writing Delphi Custom Components," and Chapter 22, "Advanced Component Techniques."

## A Dumb Wizard

To start out, you will create a very simple wizard appropriately dubbed the *Dumb wizard*. The minimum requirement in creating a wizard is to create a class that implements the `IOTAWizard` interface. For reference, `IOTAWizard` is defined in the `ToolsAPI` unit as follows:

```
type
  IOTAWizard = interface(IOTANotifier)
    ['{B75C0CE0-EEA6-11D1-9504-00608CCBF153}']
    { Expert UI strings }
    function GetIDString: string;
    function GetName: string;
    function GetState: TWizardState;
    { Launch the AddIn }
```

```
    procedure Execute;
  end;
```

This interface mainly consists of some Get*XXX()* functions that are designed to be overridden by the descendant classes in order to provide specific information for each wizard. The Execute() method is the business end of IOTAWizard. Execute() is called by the IDE when the user selects your wizard from the main menu or the New Items menu, and it is in this method that the wizard should be created and invoked.

If you have a keen eye, you may have noticed that IOTAWizard descends from another interface, called IOTANotifier. IOTANotifier is an interface defined in the ToolsAPI unit that contains methods that can be called by the IDE to notify a wizard of various occurrences. This interface is defined as the following:

```
type
  IOTANotifier = interface(IUnknown)
    ['{F17A7BCF-E07D-11D1-AB0B-00C04FB16FB3}']
    { This procedure is called immediately after the item is successfully
➥saved.
      This is not called for IOTAWizards }
    procedure AfterSave;
    { This function is called immediately before the item is saved. This is not
      called for IOTAWizard }
    procedure BeforeSave;
    { The associated item is being destroyed so all references should be
➥dropped.
      Exceptions are ignored. }
    procedure Destroyed;
    { This associated item was modified in some way. This is not called for
      IOTAWizards }
    procedure Modified;
  end;
```

As the comments in the source code indicate, most of these methods are not called for simple IOTAWizard wizards. Because of this, ToolsAPI provides a class called TNotifierObject that provides empty implementations for IOTANotifier methods. You may choose to descend your wizards from this class to take advantage of the convenience of having the IOTANotifier methods implemented for you.

Wizards are not much use without a means to invoke them, and one of the simplest ways to do that is through a menu pick. If you want to place your wizard on Delphi's main menu, you just need to implement the IOTAMenuWizard interface, which is defined in all its complexity in ToolsAPI as the following:

```
type
  IOTAMenuWizard = interface(IOTAWizard)
    ['{B75C0CE2-EEA6-11D1-9504-00608CCBF153}']
```

```
    function GetMenuText: string;
  end;
```

As you can see, this interface descends from `IOTAWizard` and adds only one additional method to return the menu text string.

To jump right in and pull together your knowledge thus far, Listing 26.1 shows the `DumbWiz.pas` unit, which contains the source code for `TDumbWizard`.

**LISTING 26.1**  `DumbWiz.pas`, a Simple Wizard Implementation

```pascal
unit DumbWiz;

interface

uses
  ShareMem, SysUtils, Windows, ToolsAPI;

type
  TDumbWizard = class(TNotifierObject, IOTAWizard, IOTAMenuWizard)
    // IOTAWizard methods
    function GetIDString: string;
    function GetName: string;
    function GetState: TWizardState;
    procedure Execute;
    // IOTAMenuWizard method
    function GetMenuText: string;
  end;

procedure Register;

implementation

uses Dialogs;

function TDumbWizard.GetName: string;
begin
  Result := 'Dumb Wizard';
end;

function TDumbWizard.GetState: TWizardState;
begin
  Result := [wsEnabled];
end;

function TDumbWizard.GetIDString: String;
begin
```

```
  Result := 'DDG.DumbWizard';
end;

procedure TDumbWizard.Execute;
begin
  MessageDlg('This is a dumb wizard.', mtInformation, [mbOk], 0);
end;

function TDumbWizard.GetMenuText: string;
begin
  Result := 'Dumb Wizard';
end;

procedure Register;
begin
  RegisterPackageWizard(TDumbWizard.Create);
end;

end.
```

The `IOTAWizard.GetName()` function should return a unique name for this wizard.

`IOTAWizard.GetState()` returns the state of a `wsStandard` wizard on the main menu. The return value of this function is a set that can contain `wsEnabled` and/or `wsChecked`, depending on how you want the menu item to appear in the IDE. This function is called every time the wizard is shown in order to determine how to paint the menu.

`IOTAWizard.GetIDString()` should return a globally unique string identifier for the wizard. Convention dictates that the return value of this string should be in the following format:

`CompanyName.WizardName`

`IOTAWizard.Execute()` invokes the wizard. As Listing 26.1 shows, the `Execute()` method for `TDumbWizard` does not do much. Later in this chapter, however, you will see some wizards that actually do perform tasks.

`IOTAMenuWizard.GetMenuText()` returns the text that should appear on the main menu. This function is called every time the user pulls down the Help menu, so it is possible to dynamically change the value of the menu text as your wizard runs.

Take a look at the call to `RegisterPackageWizard()` inside the `Register()` procedure. You might notice that this is very similar to the syntax used for registering components, component editors, and property editors for inclusion in the component library, as described in Chapter 21 and Chapter 22. The reason for this similarity is that this type of wizard is stored in a package that is part of the component library, along with components and the like. You can also store wizards in a standalone DLL, as you will see in the next example.

This wizard is installed just like a component: Select the components, Install Component option from the main menu, and add the unit to a new or existing package. Once this is installed, the menu choice to invoke the wizard appears under the Help menu, as shown in Figure 26.1. You can see the outstanding output of this wizard in Figure 26.2.

**FIGURE 26.1**

*The Dumb wizard on the main menu.*

**FIGURE 26.2**

*The Dumb wizard in action.*

## The Wizard Wizard

A little more work is involved in creating a DLL-based wizard (as opposed to a component library–based wizard). In addition to demonstrating the creation of a DLL-based wizard, the Wizard wizard example has a couple of ulterior motives, including illustrating how DLL wizards relate to the Registry and how to maintain one source code base that targets either an EXE or a DLL wizard.

> **NOTE**
>
> DLLs are discussed in greater detail in Chapter 9, "Dynamic Link Libraries."

> **TIP**
>
> There is no hard-and-fast rule that dictates whether a wizard should reside in a package in the component library or a DLL. From a user's perspective, the primary difference between the two is that component library wizards require a simple package installation to be rebuilt, whereas DLL wizards require a Registry entry, and Delphi must be exited and restarted for changes to take effect. However, as a developer, package wizards are a bit easier to deal with for a number of reasons. Namely, exceptions propagate between your wizard and the IDE automatically, you do not have to use `sharemem.dll` for memory management, you do not have to do anything special to initialize the DLL's application variable, and pop-up hints and mouse enter/exit messages will work properly.
>
> With this in mind, you should consider using a DLL wizard when you want the wizard to install with a minimum amount of work on the part of the end user.

For Delphi to recognize a DLL wizard, it must have an entry in the system Registry under the following key:

```
HKEY_CURRENT_USER\Software\Borland\Delphi\5.0\Experts
```

Figure 26.3 shows sample entries using the Windows RegEdit application.

**FIGURE 26.3**
*Delphi wizard entries viewed with RegEdit.*

## Wizard Interface

The purpose of the Wizard wizard is to provide an interface to add, modify, and delete DLL wizard entries from the Registry without having to use the cumbersome RegEdit application. First, let's examine `InitWiz.pas`, the unit containing the wizard class (see Listing 26.2).

**LISTING 26.2**   `InitWiz.pas`, the Unit Containing the DLL Wizard Class

```
unit InitWiz;

interface

uses Windows, ToolsAPI;

type
  TWizardWizard = class(TNotifierObject, IOTAWizard, IOTAMenuWizard)
    // IOTAWizard methods
    function GetIDString: string;
    function GetName: string;
    function GetState: TWizardState;
    procedure Execute;
    // IOTAMenuWizard method
    function GetMenuText: string;
  end;

function InitWizard(const BorlandIDEServices: IBorlandIDEServices;
  RegisterProc: TWizardRegisterProc;
  var Terminate: TWizardTerminateProc): Boolean stdcall;

var
  { Registry key where Delphi 5 wizards are kept.  EXE version uses default, }
  { whereas DLL version gets key from ToolServices.GetBaseRegistryKey }
  SDelphiKey: string = '\Software\Borland\Delphi\5.0\Experts';

implementation

uses SysUtils, Forms, Controls, Main;

function TWizardWizard.GetName: string;
{ Return name of expert }
begin
  Result := 'WizardWizard';
end;

function TWizardWizard.GetState: TWizardState;
{ This expert is always enabled }
```

```
begin
  Result := [wsEnabled];
end;

function TWizardWizard.GetIDString: String;
{ "Vendor.AppName" ID string for expert }
begin
  Result := 'DDG.WizardWizard';
end;

function TWizardWizard.GetMenuText: string;
{ Menu text for expert }
begin
  Result := 'Wizard Wizard';
end;

procedure TWizardWizard.Execute;
{ Called when expert is chosen from the main menu. }
{ This procedure creates, shows, and frees the main form. }
begin
  MainForm := TMainForm.Create(Application);
  try
    MainForm.ShowModal;
  finally
    MainForm.Free;
  end;
end;

function InitWizard(const BorlandIDEServices: IBorlandIDEServices;
  RegisterProc: TWizardRegisterProc;
  var Terminate: TWizardTerminateProc): Boolean stdcall;
var
  Svcs: IOTAServices;
begin
  Result := BorlandIDEServices <> nil;
  if Result then
  begin
    Svcs := BorlandIDEServices as IOTAServices;
    ToolsAPI.BorlandIDEServices := BorlandIDEServices;
    Application.Handle := Svcs.GetParentHandle;
    SDelphiKey := Svcs.GetBaseRegistryKey + '\Experts';
    RegisterProc(TWizardWizard.Create);
  end;
end;

end.
```

You should notice a couple of differences between this unit and the one used to create the Dumb wizard. Most important, an initialization function of type TWizardInitProc is required as an entry point for the IDE into the wizard DLL. In this case, that function is called InitWizard(). This function performs a number of wizard initialization tasks, including the following:

- Obtaining a IOTAServices interface from the BorlandIDEServices parameter.
- Saving the BorlandIDEServices interface pointer for use at a later time.
- Setting the handle of the DLL's Application variable to the value returned by IOTAServices.GetParentHandle(). GetParentHandle() returns the window handle of the window that must serve as the parent to all top-level windows created by the wizard.
- Passing the newly created instance of the wizard to the RegisterProc() procedure in order to register the wizard with the IDE. RegisterProc() will be called once for each wizard instance the DLL registers with the IDE.
- Optionally, InitWizard() can also assign a procedure of type TWizardTerminateProc to the Terminate parameter to serve as an exit procedure for the wizard. This procedure will be called immediately before the wizard is unloaded by the IDE, and in it you may perform any necessary cleanup. This parameter is initially nil, so if you do not need to perform any special cleanup, leave its value as nil.

> **CAUTION**
>
> The wizard initialization method must use the stdcall calling convention.

> **CAUTION**
>
> Any DLL wizards that call Open Tools API functions that have string parameters must have the ShareMem unit in their uses clause; otherwise, Delphi will raise an access violation when the wizard instance is freed.

## The Wizard User Interface

The Execute() method is a bit more complex this time around. It creates an instance of the wizard's MainForm, shows it modally, and then frees the instance. Figure 26.4 shows a picture of this form, and Listing 26.3 shows the Main.pas unit in which MainForm exists.
**FIGURE 26.4**

MainForm *in the Wizard wizard.*

**LISTING 26.3**   Main.pas, the Main Unit of the Wizard Wizard

```
unit Main;

interface

uses
  Windows, Messages, SysUtils, Classes, Graphics, Controls, Forms, Dialogs,
  StdCtrls, ExtCtrls, Registry, AddModU, ComCtrls, Menus;

type
  TMainForm = class(TForm)
    TopPanel: TPanel;
    Label1: TLabel;
    BottomPanel: TPanel;
    WizList: TListView;
    PopupMenu1: TPopupMenu;
    Add1: TMenuItem;
    Remove1: TMenuItem;
    Modify1: TMenuItem;
    AddBtn: TButton;
    RemoveBtn: TButton;
    ModifyBtn: TButton;
    CloseBtn: TButton;
    procedure RemoveBtnClick(Sender: TObject);
    procedure CloseBtnClick(Sender: TObject);
    procedure AddBtnClick(Sender: TObject);
    procedure ModifyBtnClick(Sender: TObject);
```

*continues*

**LISTING 26.3**   Continued

```
    procedure FormCreate(Sender: TObject);
  private
    procedure DoAddMod(Action: TAddModAction);
    procedure RefreshReg;
  end;

var
  MainForm: TMainForm;

implementation

uses InitWiz;

  i: integer;
  TempList: TStringList;
  Item: TListItem;
begin
  WizList.Items.Clear;
  TempList := TStringList.Create;
  try
    { Get expert names from registry }
    DelReg.GetValueNames(TempList);
    { Get path strings for each expert name }
```

*continues*

**LISTING 26.3**   Continued

```
    for i := 0 to TempList.Count - 1 do
    begin
      Item := WizList.Items.Add;
      Item.Caption := TempList[i];
      Item.SubItems.Add(DelReg.ReadString(TempList[i]));
    end;
  finally
    TempList.Free;
  end;
end;

procedure TMainForm.FormCreate(Sender: TObject);
begin
  RefreshReg;
end;

initialization
  DelReg := TRegistry.Create;          // create registry object
  DelReg.RootKey := HKEY_CURRENT_USER; // set root key
  DelReg.OpenKey(SDelphiKey, True);    // open/create Delphi expert key
finalization
  Delreg.Free;                         // free registry object
end.
```

This is the unit responsible for providing the user interface for adding, removing, and modifying DLL wizard entries in the Registry. In the `initialization` section of this unit, a `TRegistry` object called `DelReg` is created. The `RootKey` property of `DelReg` is set to `HKEY_CURRENT_USER`, and it opens the `\Software\Borland\Delphi\5.0\Experts` key—the key used to keep track of DLL wizards—using its `OpenKey()` method.

When the wizard first comes up, a `TListView` component called `ExptList` is filled with the items and values from the previously mentioned Registry key. This is accomplished by first calling `DelReg.GetValueNames()` to retrieve the names of the items into a `TStringList`. A `TListItem` component is added to `ExptList` for each element in the string list, and the `DelReg.ReadString()` method is used to read the value for each item, which is placed in the `SubItems` list of `TListItem`.

The Registry work is done in the `RemoveBtnClick()` and `DoAddMod()` methods. `RemoveBtnClick()` is in charge of removing the currently selected wizard item from the Registry. It first checks to ensure that an item is highlighted; then it throws up a confirmation dialog. Finally, it does the deed by calling the `DelReg.DeleteValue()` method and passing `CurrentItem` as the parameter.

`DoAddMod()` accepts a parameter of type `TAddModAction`. This type is defined as follows:

```
type
  TAddModAction = (amaAdd, amaModify);
```

As the values of the type imply, this variable indicates whether a new item is to be added or an existing item modified. This function first checks to see that there is a currently selected item or, if there isn't, that the `Action` parameter holds the value `amaAdd`. After that, if `Action` is `amaModify`, the existing wizard item and value are copied to the local variables `ExpName` and `ExpPath`. These values are then passed to a function called `AddModExpert()`, which is defined in the `AddModU` unit shown in Listing 26.4. This function invokes a dialog in which the user can enter new or modified name or path information for a wizard (see Figure 26.5). It returns `True` when the user exits the dialog with the OK button. At that point, an existing item is modified using `DelReg.RenameValue()`, and a new or modified value is written with `DelReg.WriteString()`.

  if OpenDialog.Execute then
    PathEd.Text := OpenDialog.FileName;
end;

end.
```

## Dual Targets: EXE and DLL

As mentioned earlier, it is possible to maintain one set of source code modules that target both a DLL wizard and a standalone executable. This is possible through the use of compiler directives in the project file. Listing 26.5 shows WizWiz.dpr, the project file source code for this project.

**LISTING 26.5**   WizWiz.dpr, Main Project File for the WizWiz Project

```
{$ifdef BUILD_EXE}
program WizWiz;      // Build as EXE
{$else}
library WizWiz;      // Build as DLL
{$endif}

uses
{$ifndef BUILD_EXE}
  ShareMem,                  // ShareMem required for DLL
  InitWiz in 'InitWiz.pas',  // Wizard stuff
{$endif}
  ToolsAPI,
  Forms,
  Main in 'Main.pas' {MainForm},
  AddModU in 'AddModU.pas' {AddModForm};

{$ifdef BUILD_EXE}
{$R *.RES}                              // required for EXE
{$else}
exports                                 // required for DLL
  InitWizard name WizardEntryPoint;     // required entry point
{$endif}

begin
{$ifdef BUILD_EXE}                      // required for EXE...
  Application.Initialize;
  Application.CreateForm(TMainForm, MainForm);
  Application.Run;
{$endif}
end.
```

As the code shows, this project will build an executable if the BUILD_EXE conditional is defined. Otherwise, it will build a DLL-based wizard. You can define a conditional under Conditional Defines in the Directories/Conditionals page of the Project, Options dialog, which is shown in Figure 26.6.

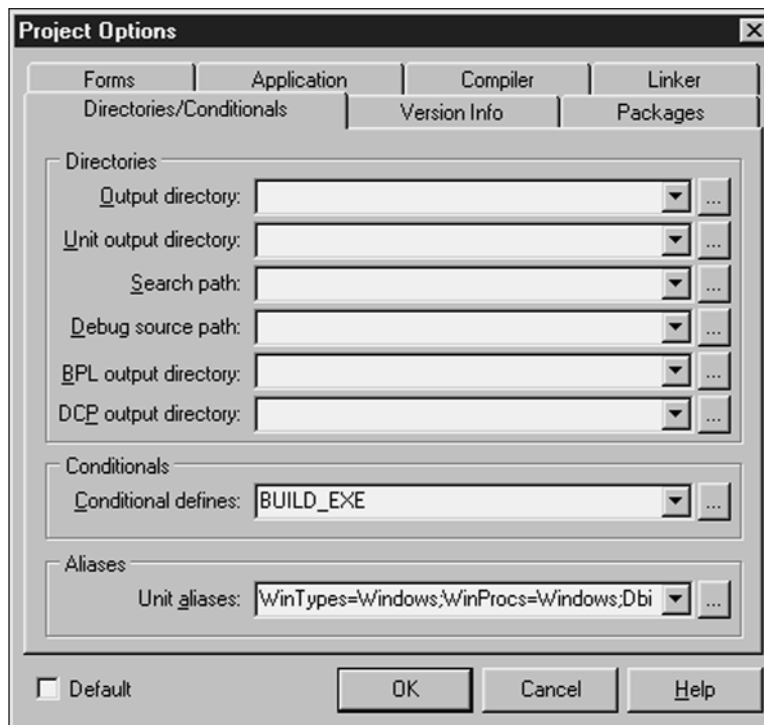

**FIGURE 26.6**
*The Project Options dialog.*

One final note concerning this project: Notice that the InitWizard() function from the InitWiz unit is being exported in the exports clause of the project file. You must export this function with the name WizardEntryPoint, which is defined in the ToolsAPI unit.

**CAUTION**

Borland does not provide a ToolsAPI.dcu file, meaning that EXEs or DLLs containing a reference to ToolsAPI in a uses clause can be built only *with packages.* Currently, it is not possible to build wizards without packages.

## DDG Search

Remember the nifty little Delphi Search program you developed back in Chapter 11, "Writing Multithreaded Applications?" In this section, you will learn how you can turn that useful application into an even more useful Delphi wizard with just a little bit of code. This wizard is called DDG Search.

First, the unit that interfaces DDG Search to the IDE, InitWiz.pas, is shown in Listing 26.6. You will notice that this unit is very similar to the unit of the same name in the previous example. That's on purpose. This unit is just a copy of the previous one with some necessary changes involving the name of the wizard and the Execute() method. Copying and pasting is what we call "old-fashioned inheritance." After all, why do more typing than you have to?

**LISTING 26.6**    InitWiz.pas, the Unit Containing Wizard Logic for the DDGSrch Wizard

```
unit InitWiz;

interface

uses
  Windows, ToolsAPI;

type
  TSearchWizard = class(TNotifierObject, IOTAWizard, IOTAMenuWizard)
    // IOTAWizard methods
    function GetIDString: string;
    function GetName: string;
    function GetState: TWizardState;
    procedure Execute;
    // IOTAMenuWizard method
    function GetMenuText: string;
  end;

function InitWizard(const BorlandIDEServices: IBorlandIDEServices;
  RegisterProc: TWizardRegisterProc;
  var Terminate: TWizardTerminateProc): Boolean stdcall;

var
  ActionSvc: IOTAActionServices;

implementation

uses SysUtils, Dialogs, Forms, Controls, Main, PriU;

function TSearchWizard.GetName: string;
{ Return name of expert }
```

*continues*

**LISTING 26.6**   Continued

```
begin
  Result := 'DDG Search';
end;

function TSearchWizard.GetState: TWizardState;
{ This expert is always enabled on the menu }
begin
  Result := [wsEnabled];
end;

function TSearchWizard.GetIDString: String;
{ Return the unique Vendor.Product name of expert }
begin
  Result := 'DDG.DDGSearch';
end;

function TSearchWizard.GetMenuText: string;
{ Return text for Help menu }
begin
  Result := 'DDG Search Expert';
end;

procedure TSearchWizard.Execute;
{ Called when expert name is selected from Help menu of IDE. }
{ This function invokes the expert }
begin
  // if not created, created it and show it
  if MainForm = nil then
  begin
    MainForm := TMainForm.Create(Application);
    ThreadPriWin := TThreadPriWin.Create(Application);
    MainForm.Show;
  end
  else
  // if created then restore window and show it
    with MainForm do
    begin
      if not Visible then Show;
      if WindowState = wsMinimized then WindowState := wsNormal;
      SetFocus;
    end;
end;

function InitWizard(const BorlandIDEServices: IBorlandIDEServices;
  RegisterProc: TWizardRegisterProc;
```

```
  var Terminate: TWizardTerminateProc): Boolean stdcall;
var
  Svcs: IOTAServices;
begin
  Result := BorlandIDEServices <> nil;
  if Result then
  begin
    Svcs := BorlandIDEServices as IOTAServices;
    ActionSvc := BorlandIDEServices as IOTAActionServices;
    ToolsAPI.BorlandIDEServices := BorlandIDEServices;
    Application.Handle := Svcs.GetParentHandle;
    RegisterProc(TSearchWizard.Create);
  end;
end;

end.
```

The Execute() function of this wizard shows you something a bit different than what you have seen so far: The wizard's main form, MainForm, is being shown modelessly rather than modally. Of course, this requires a bit of extra housekeeping, because you have to know when a form is created and when the form variable is invalid. This can be accomplished by making sure the MainForm variable is set to nil when the wizard is inactive. More on this a bit later.

One other aspect of this project that has changed significantly since Chapter 11 is that the project file is now called DDGSrch.dpr. This file is shown in Listing 26.7.

**LISTING 26.7**   DDGSrch.dpr, Project File for the DDGSrch Project

```
library DDGSrch;

uses
  ShareMem,
  ToolsAPI,
  Main in 'MAIN.PAS' {MainForm},
  SrchIni in 'SrchIni.pas',
  SrchU in 'SrchU.pas',
  PriU in 'PriU.pas' {ThreadPriWin},
  InitWiz in 'InitWiz.pas',
  MemMap in '..\..\Utils\MemMap.pas',
  StrUtils in '..\..\Utils\StrUtils.pas';

{$R *.RES}

exports
  { Entry point which is called by Delphi IDE }
```

*continues*

**LISTING 26.7** Continued

```
  InitWizard name WizardEntryPoint;

begin
end.
```

As you can see, this file is fairly small. The two important points are that it uses the `library` header to indicate that it is a DLL, and it exports the `InitWiz()` function for initialization by the Delphi IDE.

Only a couple of changes were made to the `Main` unit in this project. As mentioned earlier, the `MainForm` variable must be set to `nil` when the wizard is not active. As you learned in Chapter 2, "The Object Pascal Language," the `MainForm` instance variable will automatically have the value `nil` upon application startup. Also, in the `OnClose` event handler for the form, the form instance is released and the `MainForm` global is reset to `nil`. Here is the method:

```
procedure TMainForm.FormClose(Sender: TObject; var Action: TCloseAction);
begin
  Action := caFree;
  Application.OnShowHint := FOldShowHint;
  MainForm := nil;
end;
```

The finishing touch for this wizard is to bring up files in the IDE's Code Editor when they are double-clicked in the list box in the main form. This logic is handled by a new `FileLBDblClick()` method, as follows:

```
procedure TMainForm.FileLBDblClick(Sender: TObject);
{ Called when user double-clicks in listbox. Loads file into IDE }
var
  FileName: string;
  Len: Integer;
begin
  FileName := FileLB.Items[FileLB.ItemIndex];
  { make sure user clicked on a file... }
  if (FileName <> '') and (Pos('File ', FileName) = 1) then
  begin
    { Trim "File " and ":" from string }
    FileName := Copy(FileName, 6, Length(FileName));
    Len := Length(FileName);
    if FileName[Len] = ':' then SetLength(FileName, Len - 1);
    { Open the project or file }
    if CompareText(ExtractFileExt(FileName), '.DPR') = 0 then
      ActionSvc.OpenProject(FileName, True)
    else
```

```
      ActionSvc.OpenFile(FileName);
  end;
end;
```

This method employs the `OpenFile()` and `OpenProject()` methods of the
`IOTAActionServices` in order to open a particular file.

Listing 26.8 shows the complete source code for the `Main` unit in the `DDGSrch` project, and
Figure 26.7 shows the DDG Search wizard doing its thing inside the IDE.

**LISTING 26.8**   `Main.pas`, the Main Unit for the DDGSrch Project

```pascal
unit Main;

interface

*The DDG Search wizard in action.*

# Form Wizards

Yet another type of wizard supported by the Open Tools API is the Form wizard. Once installed, Form wizards are accessed from the New Items dialog; they generate new forms and units for the user. Chapter 24, "Extending the Windows Shell," employed this type of wizard to generate new AppBar forms; however, you did not get to see the code that made the wizard tick.

Creating a Form wizard is fairly straightforward, although you must implement a good number of interface methods. Creation of a Form wizard can be boiled down to five basic steps:

1. Create a class that descends from TCustomForm, TDataModule, or any TWinControl that will be used as the base form class. This class typically will reside in a separate unit from the wizard. In this case, TAppBar will serve as the base class.

2. Create a `TNotifierObject` descendent that implements the following interfaces: `IOTAWizard`, `IOTARepositoryWizard`, `IOTAFormWizard`, `IOTACreator`, and `IOTAModuleCreator`.

3. In your `IOTAWizard.Execute()` method, you typically will call `IOTAModuleServices.GetNewModuleAndClassName()` to obtain a new unit and class name for your wizard and `IOTAModuleServices.CreateModule()` to instruct the IDE to begin creation of the new module.

4. Many of the method implementations for the aforementioned interfaces are one-liners. The nontrivial ones include `IOTAModuleCreator`'s `NewFormFile()` and `NewImplFile()` methods, which will return the code for the form and unit, respectively. The `IOTACreator.GetOwner()` method also can be a little tricky, but the following example gives you a good technique for adding the unit to the current project (if any).

5. Complete the `Register()` procedure for the wizard by registering a handler for your new form class using the `RegisterCustomModule()` procedure in the `DsgnIntf` unit and creating your wizard by calling the `RegisterPackageWizard()` procedure in the `ToolsAPI` unit.

Listing 26.9 shows the source code for `ABWizard.pas`, which is the `AppBar` wizard.

**LISTING 26.9** `ABWizard.pas`, the Unit Containing the Implementation of the AppBar Wizard

```

```

This unit employs an interesting trick for source code generation: The unformatted source code is stored in an RES file that is linked with the $R directive. This is a very flexible way to store a wizard's source code so that it can be readily modified. The RES file is built by including a text file and RCDATA resource in an RC file and then compiling that RC file with BRCC32. Listings 26.10 and 26.11 show the contents of CodeGen.txt and CodeGen.rc.

**LISTING 26.10**    CodeGen.txt, the Resource Template for the AppBar Wizard

```
unit %0:s;

interface

uses
  Windows, Messages, SysUtils, Classes, Graphics, Controls, Forms,
  Dialogs, AppBars;
```

*continues*

**LISTING 26.10**   Continued

```
type
  T%1:s = class(%2:s)
  private
    { Private declarations }
  public
    { Public declarations }
  end;

var
  %1:s: T%1:s;

implementation

{$R *.DFM}

end.
```

**LISTING 26.11**   CODEGEN.RC

```
CODEGEN RCDATA CODEGEN.TXT
```

Registration of the custom module and wizard occurs inside a `Register()` procedure in the design package containing the wizard using the following two lines:

```
RegisterCustomModule(TAppBar, TCustomModule);
RegisterPackageWizard(TAppBarWizard.Create);
```

## Summary

After reading this chapter, you should have a greater understanding of the various units and interfaces involved in the Delphi Open Tools API. In particular, you should know and understand the issues involved in creating wizards that plug into the IDE. The next chapter, "CORBA Development with Delphi," completes this part of the book with a thorough discussion of the CORBA technology and its implementation in Delphi.
